An Intuitive Neuronal Simulator

2 ABSTRACT

Information processing by neurons relies on the transmission and interaction of electrical signals that arise from the biophysics of ion channels and synapses. Electrophysiological characterization of these mechanisms has allowed for the construction of conductance-based models that can reproduce many features of neuronal and circuit behavior. However, working with conductance-based models continues to be a challenge due to their high dimensionality, hindering intuition of their dynamical features. Here, we present a neuron and network simulator using a novel automatic type system that binds class templates written in C++ to object-oriented code in MATLAB. This approach combines the speed of C++ code with the ease-of-use of scientific programming languages like MATLAB. Neuron models are hierarchical, named and 11 searchable, permitting high-level programmatic control over all parameters. The simulator's architecture allows for the live manipulation of any parameter in any model, and for visualizing the 13 effects of changing that parameter on model behavior. The simulator is fully featured with hundreds of ion channel models from the electrophysiological literature, and can be easily extended to include arbitrary mechanisms and dynamics. Finally, the simulator is written in a modular fashion and has been released under a permissive free software license, enabling it to be integrated 17 easily in third party applications.

19 Keywords: simulator, MATLAB, C++, conductance-based, neuron, network, pedagogy

1 INTRODUCTION

- 20 Nervous systems process and transmit information through electrically-excitable membranes.
- 21 Conductance-based models are the simplest biophysical representation of an electrically-excitable cell
- 22 (Hodgkin and Huxley 1952a). Studies based on the Hodgkin-Huxley formalism now contribute signif-
- 23 icantly to mainstream research in small-circuit networks (Marder and Abbott 1995; Prinz 2006; Prinz
- 24 2010). Additionally, these models provide an approachable framework for understanding salient prin-
- 25 ciples of neuroscience. However, challenges remain in simulating biophysically-realistic neuron models.

Conductance-based models are typically high-dimensional with many coupled nonlinear differential equations. Conductances are coupled through the membrane potential, and in multicompartment models, all membrane potentials are coupled. Simulators written in languages like C, C++, or hoc integrate equations quickly, but often lack the ease-of-use and interoperability of those written in scientific programming languages (*e.g.* Python, Julia, MATLAB).

Two major approaches have dominated the design of neuron simulators. First, some simulators, such as NEURON (Hines and Carnevale 1997) are specified in a custom language with modular network components. These simulators tend to perform fast computations with little overhead, but suffer from a steep learning curve. Wrapping NEURON in a more approachable language like Python and use of graphical interfaces mitigate these drawbacks, at the cost of obfuscating the underlying algorithms and parameters (Brette et al. 2007; Hines, Davison, and Muller 2009). In contrast, many simulators have been designed to be used entirely in popular scientific programming languages. This has the benefit of ease-of-use and intercompatibility with other tools. DynaSim (Sherfey et al. 2018), Annarchy (Vitay, Dinkelbach, and Hamker 2015), BRIAN (Stimberg et al. 2013) translate strings of equations that are specified in the scientific programming language, that can be translated into a faster implementation language such as C or C++ (Stimberg et al. 2014). This approach permits considerable flexibility for simulating systems of differential equations, but the syntax tends to be verbose and the hierarchical nature of conductance-based neuron models is not naturally reflected in the user-generated code. Neither approach can maintain efficiency, ease-of-use, and clarity without sacrificing one of these aspects.

To overcome these design limitations, we have developed a novel automatic type system, cpplab, which binds MATLAB code to C++ header files. This architecture automatically creates objects in MATLAB that reflect the underlying object-oriented C++ code. xolotl is an implementation of the cpplab system specialized for integrating conductance-based neuron and network models. Models can be easily constructed from network building blocks in in a few lines of MATLAB code using hierarchical, intuitive syntax. Since objects in MATLAB are linked to the C++ implementation, changes made in MATLAB are reflected in the underlying C++ objects. xolotl comes packaged with hundreds of conductances and synapses, built-in visualization functions, and a graphical user interface (GUI) for real-time manipulation of model parameters. Plotting of voltage, intracellular calcium, conductance gating functions, and time constants is provided by built-in xolotl methods. The GUI permits real-time tuning of any network parameters using numerical sliders in a graphical interface which displays the resultant membrane potential and intracellular calcium traces. The ease-of-use of these tools lends them to pedagogical applications and rapid exploration of toy models. This tool aims to simplify the investigation of dynamics of biophysically-realistic network models, facilitate collaborative modeling, and complement other tools being developed in the neuroinformatics community.

2 DESIGN GOALS

xolotl is designed to be easy-to-use without sacrificing speed. The software is built in MATLAB due to its popularity among neuroscientists for pedagogy and research. xolotl capitalizes on MATLAB's straightforward structure array syntax to permit rapid prototyping and experimentation, especially for small neuronal networks of complex models. Parameters of conductances, cellular compartments, and simulations may all be edited in the structure before any calls to integration functions. While the underlying code is written in C++ for speed and memory optimization, symbolic manipulations can be readily performed in MATLAB without ever touching the foundational code.

2.1 FEATURES

MATLAB provides a high level programmatic and graphical interface for implementing, manipulating, and visualizing models without sacrificing the enhancements of the underlying C++ code.

69 Library of network components. xolotl comes packaged with hundreds of pre-existing components

- 70 (viz. compartments, synapses, conductances, and controllers) which greatly simplify the task of con-
- 71 structing model neurons. Compartments represent cylindrical sections of membrane with a membrane
- 72 potential. Synapses connect two compartments together by introducing a current in the post-synaptic
- 73 neuron that depends on the state of the presynaptic neuron. Conductances represent populations of ion
- channels in a compartment that produce transmembrane currents. Controllers integrate a signal from a
- 75 conductance or synapse and change the properties of the conductance or synapse in response.
- 76 *Object-oriented.* Models are specified by adding compartments and synapses to the xolotlobject. Con-
- 77 ductances are added to compartments and controllers can be added to conductances or synapses. This
- 78 modular structure recapitulates the biophysics of the Hodgkin-Huxley formalism and obviates the need to
- 79 explicitly write out equations, which in xolotl are contained within C++ header files.
- 80 Automatic type system. When a network component is added in MATLAB, the xolotl structure is
- 81 updated, and complete automatically constructs and compiles the C++ from the requisite header files.
- 82 MATLAB treats cpplab constructions as fully-typed first-class objects allowing for symbolic manipula-
- 83 tion using only the high-level programming language and graphical interfaces. xolotl simulations are
- run entirely from C++ executables; the inputs and outputs can be represented entirely in MATLAB.
- 85 Fast. xolotl is fast because all time-intensive code is written in C++. While automated C++ transpiling
- 86 from MATLAB using the proprietary codegen can drastically improve performance over loops through
- 87 strong typing and memory pre-allocation, supervenience of MATLAB over C++ prevents efficient use of
- 88 features, such as passing by reference and object-oriented programming. C++ provides speed improve-
- 89 ments beyond the benefits of translating MATLAB features into statically-typed code. For this reason,
- 90 cpplab has been designed to provide an interface for constructing, transpiling, and compiling C++ code
- 91 to be called from within MATLAB.
- 92 Automatic compiling. The user experience of xolotl can stay entirely in MATLAB. Transpiling and
- 93 compiling of C++ is performed automatically. Cryptographic hashing of the xolotl object confirms
- 94 that compiling occurs only when necessary, and that the correct binary is used during integration.

2.2 LIMITATIONS

- 95 The focus on ease-of-use and fast simulations means some features were intentionally neglected in the
- 96 streamlining process.
- 97 Limited to conductance-based models. xolotl has been developed specifically for conductance-based
- 98 models. It does not currently support rate- or current-based models.
- 99 Limited numerical integration strategies. While the exponential Euler method performs well in neuronal
- 100 models (Dayan and Abbott 2001; Oh and French 2006, it may be desirable to use other methods un-
- 101 der certain conditions. xolotl does not currently support other integration schemes for its built-in
- 102 conductances, nor does the software support error-sensitive variable step-sizes 'out-of-the-box.'
- 103 Inefficient tools for handling large networks. While xolotl can integrate large networks (> 1000 com-
- 104 partments), xolotl uses string-based comprehension for labeling compartments which is suited to
- 105 descriptive naming, but prohibits vector operations over compartments.
- 106 New mechanisms require new C++ code. Adding new network components also requires writing some
- 107 C++ code. Adding a new conductance in the Hodgkin-Huxley formalism (Dayan and Abbott 2001;

- 108 Hodgkin, Huxley, and Katz 1952), requires creating a new C++ header file, though this is generally triv-
- ial. Implementing a new integration scheme or cpplab class requires much more in-depth knowledge of
- 110 C++ and modification of the core code.

3 USAGE EXAMPLES

111 In this section, we describe several uses of xolotl for common situations.

3.1 SIMULATING A HODGKIN-HUXLEY MODEL

- 112 The seminal Hodgkin-Huxley model of action potentials in the squid giant axon (Hodgkin and Hux-
- 113 ley 1952b; Hodgkin, Huxley, and Katz 1952) contains a fast inactivating sodium conductance (NaV),
- a non-inactivating delayed rectifier (Kd), and a passive leak current (Figure 1A). This model was con-
- 115 structed using conductances from Liu et al. 1998 based on electrophysiological recordings from the
- 116 lobster stomatogastric ganglion (Turrigiano, LeMasson, and Marder 1995). A compartment, HH, with
- 117 membrane capacitance (Cm) and surface area (A) is specified by Figure 1B. Figure 1C shows the MATLAB
- 118 command window after invoking the xolotl object x, displaying the hierarchical structure inherent in
- 119 conductance-based treatments of neurodynamics.
- In the absence of applied positive current, the model is quiescent. When 0.2 nA is injected, the model
- 121 tonically spikes (Figure 1D). The integrate function takes the applied current as an argument. The
- 122 plot function generates voltage and intracellular calcium traces, where the voltage trace is colored by the
- dominant current (Figure 1E). If the membrane potential is increasing, the strongest instantaneous inward
- 124 current colors the trace. Conversely, if the membrane potential is decreasing, the strongest outward current
- 125 colors the trace instead. Figure 1F-I display the results of the show function which plots the activation
- 126 and inactivation steady-states and the voltage-dependent time constants of conductance gating variables.

3.2 PERFORMING A VOLTAGE CLAMP EXPERIMENT IN-SILICO

- 127 xolotl can recapitulate the results of voltage clamp experiments (Destexhe and Bal 2009; Swensen and
- Marder 2000, 2001; Turrigiano, LeMasson, and Marder 1995). Figure 2 displays steps in the procedure to
- 129 clamp the membrane potential of a cell with delayed rectifier potassium conductance. During an *in-vitro*
- 130 experiment, confounding currents would be pharmacologically-blocked and two-electrode voltage clamp
- 131 used to record tail currents at fixed membrane potential (Connor and Stevens 1971a,b).
- 132 A single-compartment model with a delayed-rectifier conductance (Liu et al. 1998) is simulated at
- 133 stepped membrane potentials. The integrate function outputs the membrane potential and current
- as time series. Currents under voltage clamp approach the steady-state holding current (Figure 2D-E).
- 135 The current-voltage relation is the steady-state current over the clamped voltage, and the effective con-
- ductance is the derivative of that relation (Figure 2F-G). Since the effective conductance is the product
- of the maximal conductance and the gating variables (Dayan and Abbott 2001; Turrigiano, LeMasson,
- and Marder 1995) and the tail current is monotonically-increasing with time under voltage clamp, the
- 139 current can be represented as non-inactivating. Fitting a sigmoid to various powers yields a model for
- 140 the current dynamics (Figure 2H-I). These figures describe graphically the theoretical underpinnings of
- 141 current analysis through voltage clamp and can serve as an effective pedagogical tool for computational
- 142 and quantitative neuroscience.

3.3 SIMULATING NETWORK MODELS

- 143 Network models in xolotl consist of compartment objects connected by synapses. Presynaptic and
- 144 postsynaptic labels indicate the connectivity of the synapse. Figure 3 implements a model of the triphasic
- 145 pyloric rhythm in the stomatogastric ganglion of crustaceans (Prinz, Bucher, and Marder 2004). The

- pyloric model contains three compartments and seven synapses (Figure 3A). This structure is recapitulated
- in the hierarchy of the xolotl object, where conductances are contained within compartments (Figure 147
- 3B). Synapses are stored in a vector array as a field of the xolotl object in MATLAB (Figure 3C).

SIMULATING HOMEOSTASIS

- 149 xolotl can implement homeostatic tuning rules as integral control. The controller computes an error
- 150 signal (typically a function of intracellular calcium concentration), and adjusts the conductance or synapse
- it controls accordingly (O'Leary et al. 2013). In xolotl, integral controllers are coplab objects added 151
- to the conductance or synapse they regulate. 152
- 153 In a demonstration adapted from O'Leary et al. 2013, integral control changes maximal conductances to
- bring a neuron from quiescence into a bursting regime. Calcium sensors supervene on maximal con-154
- ductance density (Figure 4) to change neuronal activity. Each conductance in the xolotl structure 155
- 156 contains a calcium-sensitive controller (Figure 4B-C). Maximal conductances increase from random ini-
- tial conditions to a set which elicits the desired network output by minimizing the error signal (Figure 157
- 158 4D-F).

USING THE GUI TO MANIPULATE PARAMETERS

- 159 The manipulate function opens the GUI which permits visualization of changing parameters in real-
- time. Moving sliders representing the values of network parameters updates a plot (Figure 5B). By default, 160
- the function opens a figure displaying the results of the plot function, which shows the voltage and 161
- intracellular calcium traces for each compartment (Figure 5A). manipulate grants slider control over 162
- all xolotl parameters by default, but specific ones can be selected by passing them as arguments. 163

BENCHMARKS

- 164 To assess speed and accuracy, xolotl, DynaSim (Sherfey et al. 2018), and NEURON (Hines and
- Carnevale 1997) were compared in simulations over varied time resolution, simulation time, and number 165
- of compartments (Figure 6). 166
- Single-compartment Hodgkin-Huxley-like models were generated using conductance dynamics from 167
- Liu et al. 1998) in the simulation environments. xolotl uses the exponential Euler method for inte-168
- grating membrane potential (Dayan and Abbott 2001). DynaSim was implemented with a 2nd-order 169
- 170 Runge-Kutta integration scheme as recommended for high-performance in the documentation. NEURON
- 171 used an implicit Euler regime (Hines and Carnevale 1997).
- To compare the integration methods, models were simulated for 5 s at varying time-resolution (Figure 172
- 6A). The ratio between 'simulated' time and actual runtime was defined as the speed factor. Higher values 173
- indicate faster simulations. The coincidence factor determines the correlative overlap between two spike 174
- trains (Jolivet et al. 2008). To assess accuracy over decreasing time-resolution for the three simulation 175
- environments, spike trains at each resolution were compared to a 'canonical' spike train (exponential 176
- Euler at a time-step of dt = 0.001 ms). 177
- 178 To assess the performance of the simulators in absence of set-up overhead, models were simulated with
- 179 a time-resolution of 0.1 ms over increasing simulation time (Figure 6B). The speed factor was defined as
- 180 the ratio between time represented in the simulation and actual runtime (simulation-time). Therefore, the
- speed factor represents how many times faster the simulation is than a real-time observation. 181
- Many simulators perform well in simulations of many compartments (Brette et al. 2007; Delorme and 182
- Thorpe 2003; Sherfey et al. 2018; Vitay, Dinkelbach, and Hamker 2015). To assess how xolot1 performs 183

- in these conditions, networks of up to 1,000 Hodgkin-Huxley cells were simulated for 5 s at a timeresolution of 0.1 ms (Figure 6C).
- 186 DESCRIBE BENCHMARK RESULTS

5 DISCUSSION

- 187 We envision that xolotl will be helpful in teaching students how to interpret cellular biophysics. The
- 188 modular structure of cpplab and the graphical interface simplifies the process of manipulating and
- analyzing the properties of electrical excitability.

5.1 REPRODUCIBILITY

- 190 xolotl fosters reproducibility in science. While the availability of hosting sites with version control (viz.
- 191 GitHub (https://github.com), GitLab (https://gitlab.com/), and Open Science Frame-
- 192 work (https://osf.io/)) and the push for reproducibility in computational science (Baker 2016;
- 193 Eklund, Nichols, and Knutsson 2016; Stodden et al. 2016) has resulted in the availability of source code,
- much of this code base is bespoke and difficult to implement (Sedano 2016; Xu, Xu, and Deng 2017).
- To this end, xolotl provides an environment with readability and reproducibility in mind. Each net-
- 196 work is hashed to provide a unique alphanumeric identifier. Conductance header files are easily viewed in
- 197 the xolotl source files; conductances in MATLAB contain links to the full path of the generating file.

5.2 CIRCUMVENTING LANGUAGE TRADEOFFS

- 198 Executing C/C++ code in higher-level languages such as MATLAB or Python often provides speed
- 199 improvements for iterative code in algorithms.
- 200 C is statically-typed, with procedural syntax that provides low-level access to memory (Kernighan and
- 201 Ritchie 1978, providing significant advantages for time-intensive computations. Unfortunately, automatic
- 202 code-generation is limited by the supervening language. MATLAB, for instance, cannot use pointers or pass
- 203 by reference, which limits the efficiency of C code automatically generated from MATLAB. Conversely,
- 204 custom C/C++ code provides significant increases in performance and memory conservation, but lacks
- 205 the ease-of-use and flexibility of scripting languages.
- 206 xolotl handles this problem through symbolic manipulation of C++ objects in MATLAB. Built from
- 207 the ground up in C++, xolotl maintains all the advantages of custom compiled code, but can run in
- 208 MATLAB without the user having to touch the C++ code. xolotl represents compartment, conductance,
- 209 synapse, and controllers as cpplab objects, which template from underlying C++ header files. In this
- 210 way, properties of the xolotl network can be examined and changed using object-oriented paradigms.
- 211 The object specifies the integrate function, not the other way around.

5.3 APPLICATIONS OF CPPLAB

212 NEED TO WRITE THIS

CONFLICT OF INTEREST STATEMENT

- 213 The authors declare that the research was conducted in the absence of any commercial or financial
- 214 relationships that could be construed as a potential conflict of interest.

AUTHOR CONTRIBUTIONS

- SG-S designed and implemented the core of the xolotl toolbox. AH contributed to the code base, 215
- created the online user documentation. SG-S and AH wrote the manuscript. EM supervised the project. 216
- 217 All authors reviewed the paper.

FUNDING

- AH received funding from National Institute on Drug Abuse (NIDA) through the undergraduate training
- grant in computational neuroscience (1R90DA033463-01).

ACKNOWLEDGMENTS

- The authors would like to thank Mara CP Rue and Hillary Rodgers for beta-testing the xolotl software.
- Janis Li helped to prepare many conductance header files.

SUPPLEMENTAL DATA

Tables including all conductances packaged with xolotl should be put in the supplementary material.

DATA AVAILABILITY STATEMENT

- The code to generate all figures is available at (https://github.com/marderlab/
- xolotl-paper). xolotl is freely available at (https://github.com/marderlab/xolotl).

FIGURE CAPTIONS

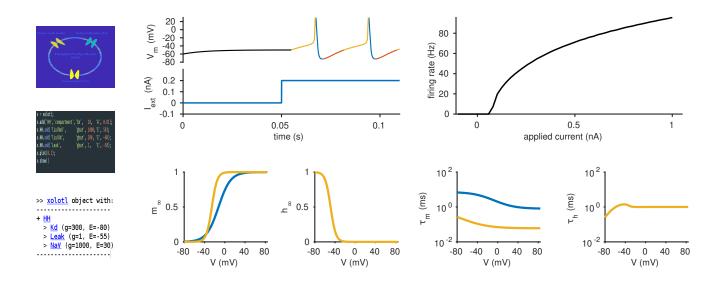

Figure 1: xolotl can quickly set up and simulate conductance-based models. (A) Cartoon of a Hodgkin-Huxley single-compartment neuron model with fast sodium, delayed rectifier, and leak currents. (B) Code snippet in MATLAB used to implement D, F-I. (C) xolotl schematic displayed in the MATLAB command prompt. (D) Simulated voltage trace of a Hodgkin-Huxley model with three conductances and 0.2 nA of injected current. Colors indicate the dominant current (gold is fast sodium, blue is delayed rectifier, red is leak). (E) Firing rate-input relation displaying firing rate as a function of injected current current. (F-G) Steady-state gating functions for activation (m) and inactivation (h) gating variables. (H-I) Voltage-dependence of time constants for activation (m) and inactivation (h) gating variables.

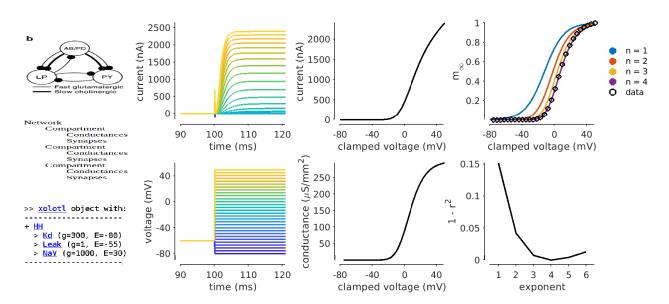

Figure 2: Simulating a voltage-clamp experiment. (A) Cartoon of a cell with delayed rectifier potassium conductance (Liu et al. 1998 with experimentally-fixed voltage. (B) Structure of xolotlobject in A. (C) Code snippet depicting integration under voltage clamp. (D-E) Current response to steps in voltage from a holding potential of $V_m = -60$ mV. (F) Current-voltage relation of the steady-state current (t = 400 ms) indicating a reversal potential of E = -80 mV and no inactivation. (G) Conductance-voltage relation at steady-state takes the form of a sigmoid. (H) Sigmoids m fit to the model as m^n data indicating that n = 4 is the best fit. (I) Goodness of fit vs. exponent n, suggesting n = 4 as the best fit to the data.

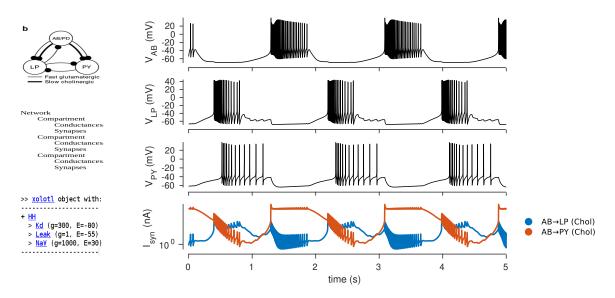

Figure 3: Simulating a network of conductance-based model neurons. (A) Diagram of a network model of the pyloric rhythm in the crustacean stomatogastric ganglion (Prinz *et al.* 2004). (B) Each neuron is modeled as a single compartment with 7-8 intrinsic conductances and 1-3 post-synaptic conductances. (C) xolotl implements conductances as fields of compartments and synapses as connections between compartments. (D-F) Simulated voltage trace of a model network for the three compartments. (G) Time series of synaptic currents in the simulated network can be obtained from the integration.

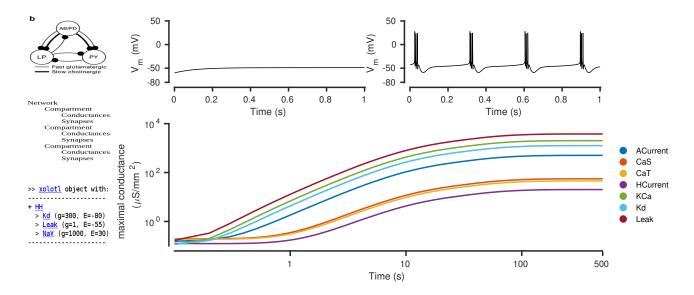

Figure 4: Simulating neurons under homeostatic regulation. (A) Cartoon of a model neuron (Liu et al. 1998 with integral control (O'Leary et al. 2013. (B) Hierarchical structure of a neuronal network considers controllers as components of compartments which act on conductances. (C) xolotl implements controllers as properties of conductances and synapses. (D) Calcium sensors change maximal conductances to move a neuron from quiescence to a bursting state. (E) Voltage trace shows regular bursting activity after integral control.

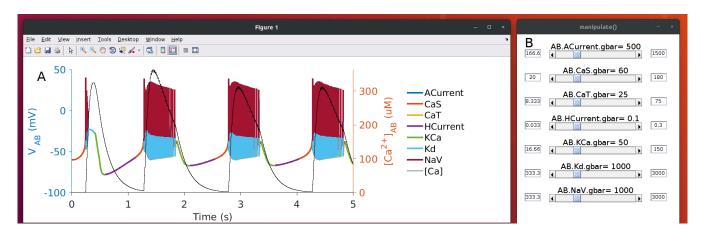

Figure 5: Using the GUI to manipulate neuron parameters. (A) Real-time output of the plot function displaying voltage (colored) and intracellular calcium (black) traces of a bursting neuron model (Prinz, Billimoria, and Marder 2003; Prinz, Bucher, and Marder 2004. Colors indicate the dominant current. (B) Sliders control the maximal conductances, which updates on the figure.

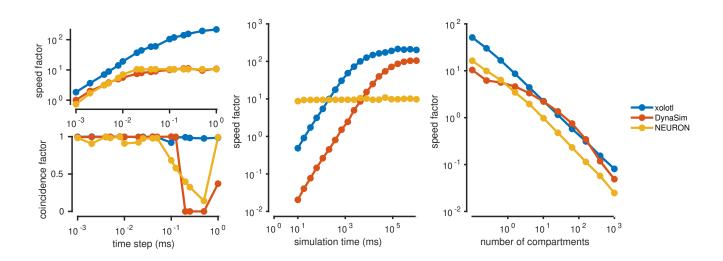

Figure 6: xolotl benchmarked against DynaSim and NEURON. (A) Ratio of 'simulated' time to runtime (speed factor) and accuracy, measured by spike train coincidence plotted against decreasing time-resolution. (B) Speed factor for models at increasing simulation times. (C) Speed factor over number of compartments.
